The dielectric characteristics of six culinary oils were measured over the frequency range of 0.01 Hz–100 kHz. The results showed that the dielectric constants of oils had the same frequency relationship (i.e., they decreased with increasing frequency). The dielectric constants at lower frequencies for olive oil A, olive oil B, sesame oil, *Nigella arvensis*, sunflower oil, and corn oil are approximately 2.75, 2.5, 2.0, 1.75, 1.5, and 0.9. An FT-IR analysis showed that the spectral differences were very small, because most vegetable oils contain the same type of fatty acids. The model built using COMSOL Multiphysics for the potential and electric field distributions for different oils and used to calculate the dielectric constant was simulated under various conditions in the AC/DC module. The model results were compared with the experimental results, which showed satisfactory convergence between them. The experimental and model results obtained in this study could be useful for evaluating the edible oil quality.

1. Introduction

The organoleptic and nutritional benefits of extra virgin olive oils have been the driving force behind their global consumption in recent decades. The preservation and assurance of extra virgin olive oil quality throughout the commercial cycle are crucial for producers, merchants, and consumers [1]. During storage, the quality of extra virgin olive oil degrades due to oxidation, causing rancidity and hydrolytic degradation, resulting in partial loss of small components [2]. Olive oil companies use chemical and sensory tests to ensure the product quality. These tests verify that the olive oil product satisfies the criteria of the customers and the quality standards set by the International Olive Council (IOC). The impact of cooking oil on the health and fitness of humans can be easily identified. The

oil quality impacts the skin and digestive system within a few days of use [3]. It directly affects the heart, blood sugar levels, and body fat percentage. This study proposes the creation of an interleaved capacitance sensor that can be used to determine fluctuations in oil capacitance by varying the frequency and temperature parameters. The dielectric constant of the oil sample was computed using the measured capacitance value [3].

Recent studies have described the use of various techniques to assess oil quality, including colorimetric reactions [4], total polar compound (TPC) measurement [5–8], and near-infrared spectroscopy [9]. The quality of fried food is associated with the oil and food used [10]. The water in frying foods reacts with air under the effect of temperature, causing chemical reactions such as oxidation, hydrolysis, and polymerization [11]. Peroxide is the principal result of
