Design Automation For Timing Driven Layout Synthesis:

Design Automation for Timing-Driven Layout Synthesis S. Sapatnekar, Sung-Mo (Steve) Kang, 2012-10-04 Moore's law Noy77 which predicted that the number of devices integrated on a chip would be doubled every two years was accurate for a number of years. Only recently has the level of integration begun to slow down somewhat due to the physical limits of integration technology. Advances in silicon technology have allowed designers to integrate more than a few million transistors on a chip even a whole system of moderate complexity can now be implemented on a single chip. To keep pace with the increasing complexity in very large scale integrated VLSI circuits the productivity of chip designers would have to increase at the same rate as the level of integration. Without such an increase in productivity the design of complex systems might not be achievable within a reasonable time frame. The rapidly increasing complexity of VLSI circuits has made design automation an absolute necessity since the required increase in productivity can only be accomplished with the use of sophisticated design tools. Such tools also enable designers to perform trade off analyses of different logic implementations and to make well informed design decisions.

An Analog VLSI System for Stereoscopic Vision Misha Mahowald, 2012-12-06 An Analog VLSI System for Stereoscopic Vision investigates the interaction of the physical medium and the computation in both biological and analog VLSI systems by synthesizing a functional neuromorphic system in silicon. In both the synthesis and analysis of the system a point of view from within the system is adopted rather than that of an omniscient designer drawing a blueprint. This perspective projects the design and the designer into a living landscape. The motivation for a machine centered perspective is explained in the first chapter. The second chapter describes the evolution of the silicon retina. The retina accurately encodes visual information over orders of magnitude of ambient illumination using mismatched components that are calibrated as part of the encoding process. The visual abstraction created by the retina is suitable for transmission through a limited bandwidth channel. The third chapter introduces a general method for interchip communication the address event representation which is used for transmission of retinal data. The address event representation takes advantage of the speed of CMOS relative to biological neurons to preserve the information of biological action potentials using digital circuitry in place of axons. The fourth chapter describes a collective circuit that computes stereodisparity. In this circuit the processing that corrects for imperfections in the hardware compensates for inherent ambiguity in the environment. The fifth chapter demonstrates a primitive working stereovision system. An Analog VLSI System for Stereoscopic Vision contributes to both computer engineering and neuroscience at a concrete level. Through the construction of a working analog of biological vision subsystems new circuits for building brain style analog computers have been developed. Specific neuropsychological and psychophysical results in terms of underlying electronic mechanisms are explained. These examples demonstrate the utility of using biological principles for building brain style computers and the significance of building brain style computers for understanding the nervous system.

Asymptotic Waveform Evaluation Eli Chiprout, Michel S. Nakhla, 1994 The intense drive for signal integrity has been at the forefront of rapid and new developments in CAD algorithms With increasing demands for high signal speeds coupled with a decrease in feature size interconnect effects such as signal delay distortion and crosstalk become the dominant factor limiting overall performance of VLSI systems Although SPICE is used on a daily basis by many engineers for analog simulation and general circuit analysis current versions of SPICE do not handle adequately the new emerging challenges of interconnect effects Moment matching techniques such as asymptotic waveform evaluation have recently proven useful in the analysis of large interconnect structures containing elements such as lossy coupled transmission lines with linear or nonlinear terminations At a CPU cost of a little more than one DC analysis these techniques are 2 3 orders of magnitude faster than full simulation techniques such as FFT Asymptotic Waveform Evaluation presents an overview of the diverse algorithms and applications of

moment matching techniques The material is presented systematically and is supported by many examples Issues such as sensitivity analysis and three dimensional analysis are also covered Asymptotic Waveform Evaluation will be of interest to engineers students and researchers involved in the development and study of circuit simulation as well as interconnect analysis It will also interest design engineers who are involved in dealing with high speed issues and graduate students who are active in the development of CAD tools for electronic systems
